Network Spellchecker

04 November, 2019

README

Description: The Network Spellchecker is a program that functions as a way to check words in a file. Users are able to do this by inputting a word of their choice which is sent to a server and compared to a dictionary of words. The server then returns the word you entered and the result expressing if it was found in the file or not. The dictionary of words contains about 20,000 various words so the likelihood that a word that you enter is in the dictionary is highly probable. One last thing to note, which is very interesting is that you as the user have the capability to run multiple instances of the program simultaneously.
